To study asymptotic behaviour of $T^n(x)$.

Introduction

Dynamical Systems

X: a space (measure, topological, manifold)

 $T: X \rightarrow X$ a map (continuous, measure-preserving, differentiable, ...).

To study asymptotic behaviour of $T^n(x)$.

Assume that there is a measure μ on X which is T-invariant. (time invariant, stationary). $(\mu(E) = \mu(T^{-1}E)$ for all measurable $E \subset X$)

L Dynamical Systems

Introduction

 $x \mapsto 2x \operatorname{map}$

X = [0, 1) with Lebesgue measure, $T : x \mapsto 2x \pmod{1}$.

Dynamical Systems

Introduction

Shift spaces

$$\begin{split} X &= \prod_{n=1}^{\infty} \mathcal{A}, \quad \mathcal{A} \text{ is a finite set.} \\ T &: (x_1 x_2 x_3 \dots) \mapsto (x_2 x_3 x_4 \dots) \text{ left-shift} \\ \mu : \text{ an invariant(stationary) measure} \end{split}$$

Fair coin tossing: (i.i.d. process)

$$X = \prod_{n=1}^{\infty} \{H, T\}, \text{ e.g., } HTHHHTHTTTT \dots \in X.$$

$$\mu(x_n = a_n \mid x_1^{n-1} = a_1^{n-1}) = \mu(x_n = a_n) = \mu(x_1 = a_n)$$
for all $n \ge 1$ and $a_n \in A^n$

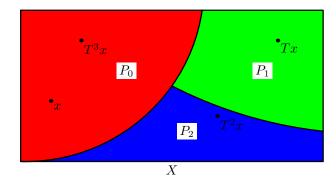

for all $n \ge 1$, and $a_1^{"} \in \mathcal{A}^{"}$. μ is a product measure on $\mathcal{A}^{\mathbb{N}}$.

(i.i.d. process \Rightarrow Chaotic or Random system)

Dynamical Systems

Introduction

 \mathcal{P} : a partition of X. (x_0, x_1, x_2, \dots): \mathcal{P} name of x if $T^i x \in P_{x_i}$, $i = 0, 1, \dots$.

 $\mathcal{P} = \{P_0, P_1, P_2\}. \ \mathcal{P} \text{ name of } x \text{ is } 0120 \dots$

 $(X, T) \iff (\{0, 1, 2\}^{\mathbb{Z}}, \sigma), \quad x \leftrightarrow 0120\dots$

Dynamical Systems

Introduction

$$X = [0,1), \ T : x \mapsto 2x \pmod{1}.$$

 (X, μ, T) is isomorphic to $(\frac{1}{2}, \frac{1}{2})$ -Bernoulli shift (coin tossing).

$$x = (x_1 x_2 x_3 \dots)_{(2)}, \quad x \leftrightarrow x_1 x_2 x_3 \dots$$

since $x_i \in 0, 1$ if $T^{i-1}x \in P_0, P_1$ respectively.

Dynamical Systems

L The Poincaré Recurrence Theorem

The Poincaré Recurrence Theorem

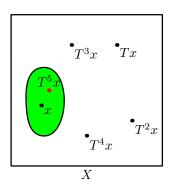

Under suitable assumptions a typical trajectory of the system comes back infinitely many times in any neighborhood of its starting point.

Dynamical Systems

L The Poincaré Recurrence Theorem

The Poincaré Recurrence Theorem

Under suitable assumptions a typical trajectory of the system comes back infinitely many times in any neighborhood of its starting point.

How many iterations of an orbit is necessary to come back within a distance *r* from the starting point?

The quantitative recurrence theory investigates this kind of questions.

Define $\tau_r(x)$ to be the first return time of x into the ball B(x, r) centered in x and with radius r.

$$\tau_r(x) = \min\{j \ge 1 : T^j(x) \in B(x,r)\}.$$

Questions:

- Distribution of τ_r . $\Pr(\tau_r(x) > s)$?
- Asymptotic limits of $\frac{\log \tau_r(x)}{-\log r}$

Define $\tau_r(x)$ to be the first return time of x into the ball B(x, r) centered in x and with radius r.

$$\tau_r(x) = \min\{j \ge 1 : T^j(x) \in B(x,r)\}.$$

Questions:

Define $\tau_r(x, y)$ to be the hitting time or waiting time of x into the ball B(y, r) centered in y and with radius r.

Waiting times, recurrence times, ergodicity and quasiperiodic dynamics LData compression scheme and the Ornstein-Weiss Theorem

Let $X = \{0,1\}^{\mathbb{N}}$ and σ be a left-shift map. Define R_n to be the first return time of the initial *n*-block, i.e.,

$$R_n(x) = \min\{j \ge 1 : x_1 \dots x_n = x_{j+1} \dots x_{j+n}\}.$$

$$x = \underbrace{\overbrace{1010}^{15}}_{101001101100} \underbrace{1010}_{1010} \dots \Rightarrow R_4(x) = 15.$$

The convergence of $\frac{1}{n} \log R_n(x)$ to the entropy *h* was studied in a relation with data compression algorithm such as the Lempel-Ziv compression algorithm.

Lempel-Ziv data compression algorithm

The Lempel-Ziv data compression algorithm provide a universal way to coding a sequence without knowledge of source. Parse a source sequence into shortest words that has not appeared so far:

 $1011010100010 \dots \Rightarrow 1, 0, 11, 01, 010, 00, 10, \dots$

For each new word, find a phrase consisting of all but the last bit, and recode the location of the phrase and the last bit as the compressed data.

(000, 1) (000, 0) (001, 1) (010, 1) (100, 0) (010, 0) (001, 0)...

Theorem (Wyner-Ziv(1989), Ornstein and Weiss(1993)) For ergodic processes with entropy h,

$$\lim_{n\to\infty}\frac{1}{n}\log R_n(x)=h \quad almost \ surely.$$

Theorem (Wyner-Ziv(1989), Ornstein and Weiss(1993)) For ergodic processes with entropy h,

$$\lim_{n\to\infty}\frac{1}{n}\log R_n(x)=h \quad almost \ surely.$$

The meaning of entropy

- Entropy measures the information content or the amount of randomness.
- Entropy measures the maximum compression rate.
- Totally random binary sequence has entropy log 2 = 1. It cannot be compressed further.

Waiting times, recurrence times, ergodicity and quasiperiodic dynamics $\hfill Data$ compression scheme and the Ornstein-Weiss Theorem

The Shannon-McMillan-Brieman theorem states that

$$\lim_{n\to\infty}-\frac{1}{n}\log P_n(x)=h \quad \text{a.e.},$$

where $P_n(x)$ is the probability of $x_1x_2...x_n$.

If the entropy h is positive,

$$\lim_{n\to\infty}\frac{\log R_n(x)}{-\log P_n(x)}=1 \quad \text{ a.e.}$$

For many hyperbolic (chaotic) systems

$$\lim_{r\to 0^+}\frac{\log\tau_r(x)}{-\log r}=d_\mu(x),$$

where d_{μ} is the local dimension of μ at x. (Saussol, Troubetzkoy and Vaienti (2002), Barreira and Saussol (2001, 2002), G.H. Choe (2003), C. Kim and D. H. Kim (2004))

What happens, if h = 0, which implies that $\log R_n$ and $\log P_n$ do not increases linearly.

 $T: x \mapsto x + \theta \pmod{1}$, an irrational rotation.

 $T: x \mapsto x + \theta \pmod{1}$, an irrational rotation.

$$|T^q x - x| < \delta \quad \Rightarrow \quad |q\theta - \exists p| < \delta \quad \Rightarrow \quad \left|\theta - \frac{p}{q}\right| < \frac{\delta}{q}.$$

Diophantine approximation:

$$\left|\theta-\frac{p}{q}\right|<\frac{1}{\sqrt{5}q^2}.$$

An irrational number θ , $0 < \theta < 1$, is said to be of type η if

$$\eta = \sup\{\beta: \liminf_{j\to\infty} j^\beta \| j\theta\| = 0\},$$

- $\|\cdot\|$ is the distance to the nearest integer $(\|t\| = \min_{n \in \mathbb{Z}} |t n|)$.
 - Note that every irrational number is of type η ≥ 1. The set of irrational numbers of type 1 (Called Roth type) has measure 1.
 - A number with bounded partial quotients is of type 1.
 - ► There exist numbers of type ∞ , called the Liouville numbers. For example $\theta = \sum_{i=1}^{\infty} 10^{-i!}$.

Let $T(x) = x + \theta \pmod{1}$ on [0, 1) for an irrational θ of type η , Theorem (Choe-Seo (2001))

For every x

$$\liminf_{r\to 0^+} \frac{\log \tau_r(x)}{-\log r} = \frac{1}{\eta}, \quad \limsup_{r\to 0^+} \frac{\log \tau_r(x)}{-\log r} = 1.$$

Theorem (K-Seo (2003))

For almost every y

$$\limsup_{r \to 0^+} \frac{\log \tau_r(x, y)}{-\log r} = \eta, \qquad \liminf_{r \to 0^+} \frac{\log \tau_r(x, y)}{-\log r} = 1.$$

LInfinite invariant measure systems

Infinite invariant measure systems

- Such systems are used for models of statistically anomalous phenomena such as intermittency and anomalous diffusion and they do have interesting statistical behavior.
- Many classical theorems of finite measure preserving systems from ergodic theory can be extended to the infinite measure preserving case.
- ▶ The Hopf ratio ergodic theorem: Let T be conservative and ergodic and $f, g \in L^1$ such that $\int g d\mu \neq 0$, then

$$\frac{\sum_{k=0}^{n-1} f(T^k(x))}{\sum_{k=0}^{n-1} g(T^k(x))} \to \frac{\int f d\mu}{\int g d\mu}, \quad \text{a.e.}$$

(日) (同) (三) (三) (三) (○) (○)

Entropy for infinite invariant measure systems

Let T be a conservative, ergodic measure preserving transformation on a σ -finite space (X, A, μ) . Then the entropy of T can be defined as

$$h_{\mu}(T) = \mu(Y)h_{\mu_Y}(T_Y)$$

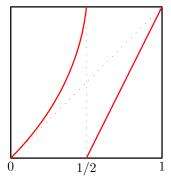

where $Y \in \mathcal{A}$ with $0 < \mu(Y) < \infty$ and T_Y is the induced map of $Y(T_Y(x) = T^{R_Y(x)})$ where

$$R_{\mathbf{Y}}(x) = \min\{n \ge 1 : T^n(x) \in \mathbf{Y}\}$$

when $x \in Y$) and μ_Y is the induced measure $(\mu_Y(E) = \frac{\mu(E \cap Y)}{\mu(Y)})$ which is invariant and ergodic under T_Y .

Manneville-Pomeau map

The Manneville-Pomeau map

$$F(x) = egin{cases} x+2^{z-1}x^z, & 0 \le x < 1/2, \ 2x-1, & 1/2 \le x < 1. \end{cases}$$

have an indifferent "slowly repulsive" fixed point at the origin. When $z \in [2, \infty)$ this forces the natural invariant measure for this map to be infinite and absolutely continuous with respect to Lesbegue.

It is not hard to see that $\mathcal{P} = \{[0, 1/2), [1/2, 1)\}$ is a generating partition and the entropy $h_{\mu}(T)$ is positive and finite.

Shannon-McMillan-Breiman Theorem

For every
$$f \in L^1(\mu)$$
, with $\int f \neq 0$
$$\frac{-\log(\mu(P_n(x)))}{S_n(f,x)} \to \frac{h_\mu(T)}{\int f d\mu} \text{ a.e. as } n \to \infty.$$

Here $S_n(f, x)$ is the partial sums of f along the orbit of x:

$$S_n(f,x) = \sum_{k \in [0,n-1]} f(T^k(x)).$$

("information content" growing as a sublinear power law as time increases)

> (X, T, A, μ) : a measure preserving system. Let ξ be a partition of X and A be an atom of ξ . Let $S_n(A, x)$ be the number of $T^i x \in A$ for $0 \le i \le n - 1$, i.e.,

$$S_n(A, x) = S_n(1_A, x) = \sum_{i=0}^{n-1} 1_A(T^i(x)).$$

Define

$$R_n(x) = \min\{j \ge 1 \mid \xi_n(x) = \xi_n(T^j x)\}$$

considering a fixed set $A \in \mathcal{A}$ we also define $\overline{R}_n(x)$ by

$$\overline{R}_n(x) = \min\{S_j(A, x) \ge 1 \mid \xi_n(x) = \xi_n(T^j x)\}.$$

Note that

$$\bar{R}_n(x)=S_{R_n(x)}(A,x).$$

Lemma

Let T be a conservative, ergodic measure preserving transformation (c.e.m.p.t.) on the σ -finite space (X, \mathcal{B}, μ) and let ξ be a finite generating partition (mod μ). Assume that there is a subset A which is a union of atoms in ξ with $0 < \mu(A) < \infty$ and $H(\xi_A) < \infty$. For almost every $x \in A$

$$\lim_{n\to\infty}\frac{\log \bar{R}_n(x)}{S_n(A,x)}=\frac{h_\mu(T)}{\mu(A)}.$$

Let ξ_A be the induced partition on A,

$$\xi_A = \cup_{k\geq 1} \{V \cap \{R_A = k\} : V \in A \cap \xi_k\}.$$

Theorem (Galatolo-K-Park (2006))

Let T be a c.e.m.p.t. on the σ -finite space (X, \mathcal{B}, μ) and let $\xi \subset \mathcal{B}$ be a finite generating partition (mod μ). Assume that there is a subset A which is a union of atoms in ξ with $0 < \mu(A) < \infty$ and $H(\xi_A) < \infty$. Then for any $f \in L^1(\mu)$ with $\int fd\mu \neq 0$,

$$\limsup_{n\to\infty}\frac{\log R_n(x)}{S_n(f,x)}=\frac{h_\mu(T)}{\alpha\int fd\mu} \quad a.e.,$$

where

$$\alpha = \sup_{0 < \mu(B) < \infty, B \in \mathcal{B}} \left(\sup\{\beta : \int_{B} (R_B)^{\beta} d\mu < \infty\} \right).$$

Moreover, if $\alpha = 0$, then the limsup goes to infinity.

Darling-Kac set

A set A is called a Darling-Kac set, if $\exists \{a_n\}$ such that

$$\lim_{n\to\infty}\frac{1}{a_n}\sum_{k=1}^n \hat{T}^k 1_A = \mu(A), \quad \text{almost uniformly on } A.$$

A function f is slowly varying at ∞ if $\frac{f(xy)}{f(x)} \to 1$ as $x \to \infty, \forall y > 0$. Suppose that T has a Darling-Kac set and $a_n(T) = n^{\alpha}L(n)$, where L(n) is a slowly varying. The Darling-Kac Theorem states

$$\frac{S_n(x)}{a_n(T)} \to Y_{\alpha}$$
, in distribution,

 Y_{α} : the normalized Mittag-Leffler distribution of order α .

Recurrence time of infinite invariant measure systems

Manneville-Pomeau map

Theorem (Galatolo-K-Park (2006))

Let T be a c.e.m.p.t. on the σ -finite space (X, \mathcal{B}, μ) and let $\xi \subset \mathcal{B}$ be a finite generating partition (mod μ). Assume that there is a subset A which is a union of atoms in ξ with $0 < \mu(A) < \infty$ and $H(\xi_A) < \infty$. Suppose that T has a Darling-Kac set and $a_n(T)$ is regularly varying with index α . Then for any $f \in L^1(\mu)$ with $\int f\mu \neq 0$,

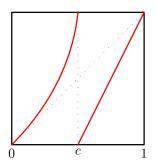

$$\lim_{n \to \infty} \frac{\log R_n(x)}{S_n(f,x)} = \frac{h_\mu(T)}{\alpha \int f d\mu} \quad a.e.$$

Moreover, if $\alpha = 0$, then the limit goes to infinity.

A map $T : [0, 1] \rightarrow [0, 1]$ is a Manneville-Pomeau map (MP map) with exponent z if it satisfies the following conditions:

▶ there is $c \in (0, 1)$ such that, if $I_0 = [0, c]$ and $I_1 = (c, 1]$, then $T|_{(0,c)}$ and $T|_{(c,1)}$ extend to C^1 diffeomorphisms, $T(I_0) = [0, 1]$, $T(I_1) = (0, 1]$ and T(0) = 0;

- ▶ there is $\lambda > 1$ such that $T' \ge \lambda$ on I_1 , whereas T' > 1 on (0, c] and T'(0) = 1;
- ► the map T has the following behaviour when x → 0⁺

$$T(x) = x + rx^{z} + o(x^{z})$$

for some constant r > 0 and z > 1.

When z ≥ 2 these maps have an infinite, absolutely continuous invariant measure µ with positive density and the entropy can be calculated as h_µ(T) = ∫_[0,1] log(T')dµ.

- ▶ When $z \ge 2$ these maps have an infinite, absolutely continuous invariant measure μ with positive density and the entropy can be calculated as $h_{\mu}(T) = \int_{[0,1]} \log(T') d\mu$.
- These maps have DK sets where the first return map is mixing and hence they satisfy the assumptions of the above section.

- ▶ When $z \ge 2$ these maps have an infinite, absolutely continuous invariant measure μ with positive density and the entropy can be calculated as $h_{\mu}(T) = \int_{[0,1]} \log(T') d\mu$.
- These maps have DK sets where the first return map is mixing and hence they satisfy the assumptions of the above section.
- If z > 2, we have a behavior of the return time sequence

$$a_n(T) = n^{1/(z-1)}L(n),$$

where L(n) is a slowly varying function.

- When z ≥ 2 these maps have an infinite, absolutely continuous invariant measure µ with positive density and the entropy can be calculated as h_µ(T) = ∫_[0,1] log(T')dµ.
- These maps have DK sets where the first return map is mixing and hence they satisfy the assumptions of the above section.
- If z > 2, we have a behavior of the return time sequence

$$a_n(T) = n^{1/(z-1)}L(n),$$

where L(n) is a slowly varying function.

• Setting $S_n(x) = \sum_{i \le n} \mathbb{1}_{I_1}(T^i(x))$, we have

$$\lim_{n\to\infty}\frac{\log R_n(x)}{S_n(x)}=\frac{h_{\mu}(T)}{\mu(I_1)}(z-1).$$

Theorem (Galatolo-K-Park (2006))

Let (X, T, ξ) satisfy (1)-(3) and μ be the absolutely continuous invariant measure then

$$\lim_{r \to 0} \frac{\log \tau_r(x)}{-\log r} = \begin{cases} 1 & \text{if } z \le 2\\ z - 1 & \text{if } z > 2 \end{cases}$$

for almost all points x (recall that $\tau_r(x)$ is the first return time of x in the ball B(x, r)).
